GASTROENTERITIS AGGRESSIVE VERSUS  
SLOW TREATMENT FOR REHYDRATION

Prof Kathryn Maitland  
on behalf of the GASTRO team

---

wellcome trust

---

MCRI

# Gastroenteritis

- 2.5 billion cases worldwide in children under 5years
- Second biggest killer of children in this age group
- Children hospitalised in LIMC with **GE are 8.5 times** more likely to die than their non-GE counterparts
- **1/3<sup>rd</sup> of fatalities occurred <7 days following admission**
- Are initial treatment recommendations working in practice?

# GE fluid management: according to severity of dehydration

Table 12. Classification of the severity of dehydration in children with diarrhoea

Classification	Signs or symptoms	Treatment
<b>Severe dehydration</b>	Two or more of the following signs: <ul style="list-style-type: none"> <li>■ lethargy or unconsciousness</li> <li>■ sunken eyes</li> <li>■ unable to drink or drinks poorly</li> <li>■ skin pinch goes back very slowly (<math>\geq 2</math> s)</li> </ul>	<ul style="list-style-type: none"> <li>▶ Give fluids for severe dehydration (see diarrhoea treatment plan C in hospital, p. 131)</li> </ul>
<b>Some dehydration</b>	Two or more of the following signs: <ul style="list-style-type: none"> <li>■ restlessness, irritability</li> <li>■ sunken eyes</li> <li>■ drinks eagerly, thirsty</li> <li>■ skin pinch goes back slowly</li> </ul>	<ul style="list-style-type: none"> <li>▶ Give fluid and food for some dehydration (see diarrhoea treatment plan B, p. 135)</li> <li>▶ After rehydration, advise mother on home treatment and when to return immediately (see pp. 133–4)</li> <li>▶ Follow up in 5 days if not improving.</li> </ul>
<b>No dehydration</b>	Not enough signs to classify as some or severe dehydration	<ul style="list-style-type: none"> <li>▶ Give fluid and food to treat diarrhoea at home (see diarrhoea treatment plan A, p. 138)</li> <li>▶ Advise mother on when to return immediately (see p. 133)</li> <li>▶ Follow up in 5 days if not improving.</li> </ul>

Kenya 13 hospitals report

- GE+ Severe dehydration : n=8562

➤ **Mortality 9%** (759 died)

➤ If shock present mortality =34%

➤ Indicated not getting fluid management risk

factor: confirmation bias?

Lancet CAH 2018

## Risk factors for mortality and effect of correct fluid prescription in children with diarrhoea and dehydration without severe acute malnutrition admitted to Kenyan hospitals: an observational, association study

Samuel Akech, Philip Ayieko, David Gathara, Ambrose Agweyu, Grace Irimu, Kasia Stepniowska, Mike English, on behalf of the Clinical Information Network authors\*

# Rehydration guidelines: WHO Plan C

# Current Guidelines (WHO 2013)

## Severe dehydration

(only in a child with diarrhoea)

Diarrhoea plus any two of these signs:

- Lethargy
- Sunken eyes
- Very slow skin pinch
- Unable to drink or drinks poorly

**DIARRHOEA PLUS**

**two signs positive**

Check for severe malnutrition

▶ Make sure the child is warm.

### If no severe malnutrition:

▶ Insert an IV line and begin giving fluids rapidly following Chart 11 and diarrhoea treatment plan C in hospital (Chart 13, p. 131).

### If severe malnutrition:

- ▶ Do not insert an IV line.
- ▶ Proceed immediately to full assessment and treatment (see section 1.4, p. 19).

## 'Plan C'

100mls/kg Ringers Lactate  
 ~ vol to correct '10% dehydration'  
 2-staged approach  
 2-rates according to age

**Table 13. Administration of intravenous fluids to a severely dehydrated child**

Age (months)	First, give 30 ml/kg in:	Then, give 70 ml/kg in:
< 12	1 h <sup>a</sup>	5 h
≥ 12	30 min <sup>a</sup>	2.5 h

<sup>a</sup> Repeat if the radial pulse is still very weak or not detectable.

# The devil is in the detail....3 charts later....

## Severe dehydration

(only in a child with diarrhoea)

Diarrhoea plus any two of these signs:

- Lethargy
- Sunken eyes
- Very slow skin pinch
- Unable to drink or drinks poorly

**DIARRHOEA PLUS**

**two signs positive**

Check for severe malnutrition

- ▶ Make sure the child is warm.
- If no severe malnutrition:**
  - ▶ Insert an IV line and begin giving fluids rapidly following Chart 11 and diarrhoea treatment plan C in hospital (Chart 13, p. 131).
- If severe malnutrition:**
  - ▶ Do not insert an IV line.
  - ▶ Proceed immediately to full assessment and treatment (see section 1.4, p. 19).

## Chart 11. How to treat severe dehydration in an emergency after initial management of shock

For children with severe dehydration but without shock, refer to diarrhoea treatment plan C, p. 131.

If the child is in shock, first follow the instructions in Charts 7 and 8 (pp. 13 and 14). Switch to the chart below when the child's pulse becomes slower or capillary refill is faster.

- ▶ Give 70 ml/kg of Ringer's lactate (Hartmann's) solution (or, if not available, normal saline) over 5 h to infants (aged < 12 months) and over 2.5 h to children (aged 12 months to 5 years).

## Chart 7. How to give intravenous fluids to a child in shock without severe malnutrition

- ▶ Check that the child is not severely malnourished, as the fluid volume and rate are different. (Shock with severe malnutrition, see Chart 8.)
- ▶ Insert an IV line (and draw blood for emergency laboratory investigations).
- ▶ Attach Ringer's lactate or normal saline; make sure the infusion is running well.
- ▶ Infuse 20 ml/kg as rapidly as possible.

### Reassess the child after the appropriate volume has run in.

Reassess after first infusion:	<ul style="list-style-type: none"> <li>• If no improvement, repeat 10–20 ml/kg as rapidly as possible.</li> <li>• If bleeding, give blood at 20 ml/kg over 30 min, and observe closely.</li> </ul>
Reassess after second infusion:	<ul style="list-style-type: none"> <li>• If no improvement with signs of dehydration (as in profuse diarrhoea or cholera), repeat 20 ml/kg of Ringer's lactate or normal saline.</li> <li>• If no improvement, with suspected septic shock, repeat 20 ml/kg and consider adrenaline or dopamine if available (see Annex 2, p. 353).</li> <li>• If no improvement, see disease-specific treatment guidelines. You should have established a provisional diagnosis by now.</li> </ul>

Up to 3 boluses of 20mls/kg

# WHO Plan C: management of severe dehydration

## Integrated management of dehydration?

Chart 2 (Triage Page 6)

Chart 7 (Shock treatment Page 13)

Chart 8 (kids with SAM; Page 14)

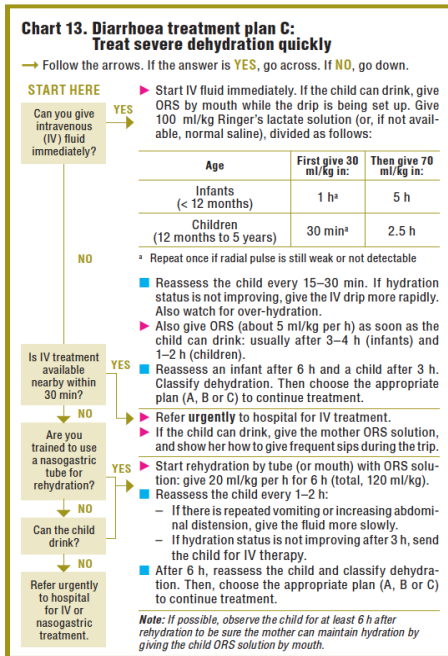

Chart 11 (Post shock Rx) Page 17

Chart 13 (WHO Plan C Page 141)

So lets do the Maths: Shock + Severe Dehydration

✓ Correctly followed 100-130mls/kg

➤ 'Incorrectly' followed 120-160mls/kg

**Table 13. Administration of intravenous fluids to a severely dehydrated child**

Age (months)	First, give 30 ml/kg in:	Then, give 70 ml/kg in:
< 12	1 h <sup>a</sup>	5 h
≥ 12	30 min <sup>a</sup>	2.5 h

Repeat if the radial pulse is still very weak or not detectable.

Maths did not include this bit!

ABSTRACT

Fast track; May 2011

Submitted to NEJM April 15<sup>th</sup>: **3 months after IDMC stop**

# Unresolved questions arising from FEAST

## **What were the study hypotheses?**

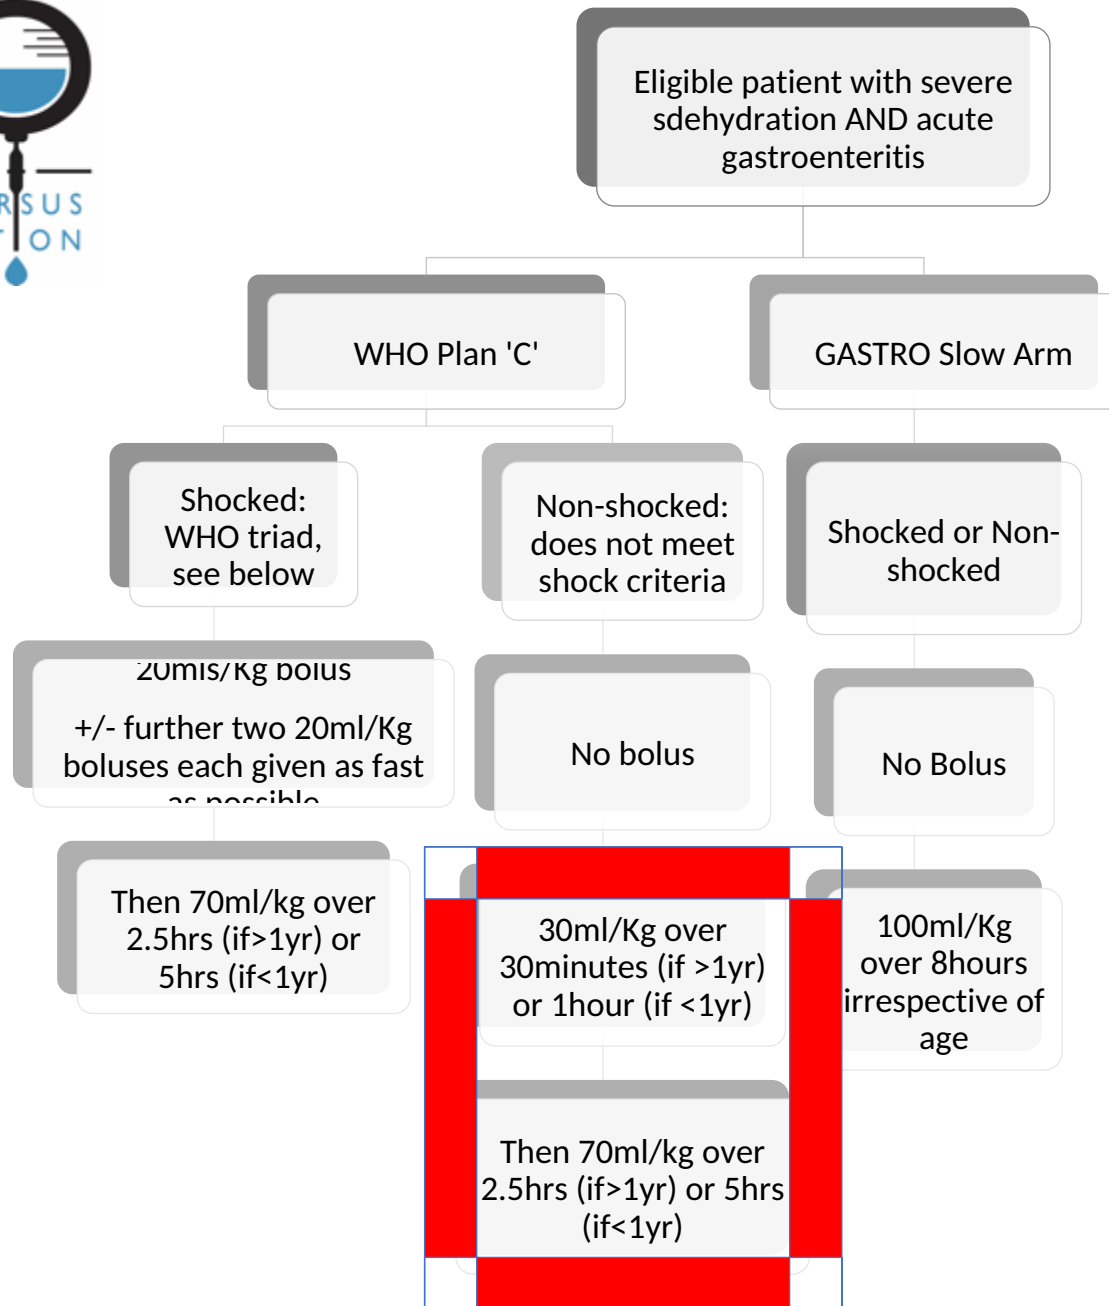

In children with diarrhoea and severe dehydration

- 1) Could the rehydration guideline be simplified?
- 2) As FEAST showed harm of fluid bolus therapy could this be extended to children with GE management by Plan C?

## Accuracy of signs of severe dehydration (~10% loss)\*

	WHO plan C	GASTRO slow	Total
<b>N</b>	58	57	115
<b>Mean (sd)</b>	6 (6)	7 (6)	7 (6)
<b>Median (IQR)</b>	6 (2, 11)	5 (3, 10)	6 (2, 11)
<b>0-5% - n (%)</b>	24 (41)	28 (42)	52 (45)
<b>5-10% - n (%)</b>	17 (29)	13 (23)	30 (26)
<b>10% - n (%)</b>	17 (29)	16 (28)	33 (29)

\* Relevance

- On Day 7 all children (without on going losses) were reweighed.
- Day 7 weight was a proxy for pre-illness weight

# Diagnostic accuracy of three clinical dehydration scales: a systematic review

Anna Falszewska, Hania Szajewska, Piotr Dziechciarz

## What this study adds?

- ▶ The CDS provides a moderate-to-large increase in the post-test probability of predicting moderate-to-severe ( $\geq 6\%$ ) dehydration only in developed countries.
- ▶ The WHO and Gorelick Scales are not helpful in the assessment of dehydration both in developed and developing countries.

LIMC: Rwanda 2 studies – same authors

# Findings

- Hypernatraemic dehydration is more common than considered in current guidelines: but appeared to be safely managed in trial on same regime
  - Accuracy of signs of dehydration: only 30% actually had equivalent of 10% loss
  - Slow rehydration (no boluses) safe and easier to implement than Plan C
  - Adherence to WHO Plan C required lots of training and monitoring
- Many enrolled 'not eligible' as just qualified as severe malnutrition due to 10% dehydration (MUAC and WHZ) but once rehydrated no longer classified as SAM

## Implications for evidence

- Emergency treatment (bolus) plus WHO Plan C may result in large volumes given over short period time (very low quality of evidence)
- Poor outcomes, low quality evidence base and new findings: rationale for a Phase III trial

[Background](#)

- ✓ Slower rehydration is safe and easier to implement than two stage WHO Plan C
- ✓ Need for Phase III RCT that includes both SAM and non-SAM

Severe malnutrition?

# SAM: WHO guideline highlight cardiac compromise

Over the last 2 decades guidelines not changed/update suggesting:

- Heart is 'shrunken'
- Unable to cope with volume (intravenous)
- Children with SAM are sodium overloaded
- IV infusions can precipitate heart failure (including severe dehydration)
- Children with kwashiorkor are particularly at risk
- At risk of refeeding syndrome (cardiac arrhythmias)
- Expert opinion; low quality of evidence AND NOT UPDATED with evolving research

# Response to fluid rehydration therapy?

Over time SVRI improved/normalized; Stroke volume improved with iv fluids

Frank Starling Curves= Fluid responsive

## Bottomline:

- ✓ No child developed cardiac overload or received diuretics:
- ✓ All cardiac parameters showed a positive response to fluids

# In conclusion

- We found no evidence that children with SAM were more likely to have cardiac dysfunction or arrhythmias than matched controls,
- Nor that the cardiovascular profile of marasmus differed from kwashiorkor.
- No evidence for clinical cardiac failure or sudden death from arrhythmias in our study.
- Appropriate physiological response observed to IV fluids are better tolerated than current guidelines suggest

## ABSTRACT

**Objective** Cardiac dysfunction may contribute to high mortality in severely malnourished children. Our objective was to assess the effect of malnutrition on cardiac function in hospitalised African children.

**Design** Prospective cross-sectional study.

**Setting** Public referral hospital in Blantyre, Malawi.

**Patients** We enrolled 272 stable, hospitalised children ages 6–59 months, with and without WHO-defined severe acute malnutrition.

**Main outcome measures** Cardiac index, heart rate, mean arterial pressure, stroke volume index and systemic vascular resistance index were measured by the ultrasound cardiac output monitor (USCOM, New South Wales, Australia). We used linear regression with generalised estimating equations controlling for age, sex and anaemia.

**Results** Our primary outcome, cardiac index, was similar between those with and without severe malnutrition: difference=0.22 L/min/m<sup>2</sup> (95% CI –0.08 to 0.51). No difference was found in heart rate or stroke volume index. However, mean arterial pressure and systemic vascular resistance index were lower in children

## What is known on this topic

- ▶ Children hospitalised with severe acute malnutrition have a very high mortality rate.
- ▶ The effect of severe malnutrition on cardiac function is controversial.
- ▶ Fluid management in severely malnourished children is also controversial.

## What this study adds

- ▶ Cardiac index is preserved in *stable*, hospitalised children with WHO defined severe acute malnutrition.
- ▶ When children are stratified by degree of wasting, cardiac index *increases* with worsening nutritional status, commensurate with a lower systemic vascular resistance index.

## What this study adds

- ▶ Cardiac index is preserved in *stable*, hospitalised children with WHO defined severe acute malnutrition.
- ▶ When children are stratified by degree of wasting, cardiac index *increases* with worsening nutritional status, commensurate with a lower systemic vascular resistance index.

# Why does this matter?

WHO Guidelines:

- **“Giving iv fluids put SAM children at risk of overhydration and complications like heart failure”. ?**
- SAM Children with acute diarrhoea and severe dehydration are not given IV fluids, only those with signs of decompensated shock.
- 15mls/kg Half strength Ringers lactate, half strength Darrow’s solution in 5% dextrose or 0.45% saline are the recommended solutions

SYSTEMATIC REVIEW

# Intravenous rehydration of malnourished children with acute gastroenteritis and severe dehydration: A systematic review

[version 1; referees: 3 approved]

Kirsty A. Houston<sup>1,2</sup>, Jack G. Gibb<sup>1,2</sup>, Kathryn Maitland  <sup>1,2</sup>

4 studies were identified = 883 children conducted in low resource settings.

2 were RCT 2 two observational cohort studies, 1 incorporated assessment of myocardial function (AFRIM).

**No evidence of fluid overload or other fluid-related adverse events,**

In African children Mortality was high overall, particularly in **children managed on WHO protocol (day-28 mortality 82%).**

There was no difference in safety outcomes when different rates of intravenous rehydration were compared.

**Conclusions: The current 'strong recommendations' for conservative rehydration of children with SAM are not based on emerging evidence.**
